

Bond Price Volatility

Financial Engineering and Computations

Dai, Tian-Shyr

此章內容

- Financial Engineering & Computation教課書的第四章 Bond Price Volatility
- C++財務程式設計的第三章 (3-4,3-5)

Outline

- Price Volatility
- Duration
- Convexity
- Immunization

Price Volatility

- Price volatility measures the sensitivity of the percentage price change to changes in interest rates (interest rate risk).
- It is key to the risk management of interest-rate-sensitive securities.
- Define price volatility by

$$-\frac{\partial P / P}{\partial y} \longrightarrow \text{It is also so-call modified duration!}$$

$$\frac{\partial P}{P} (\text{percent price change}) \approx -D \times \partial y$$

Numerical Example: Percentage Change of Bond Price

- Consider a bond whose modified duration is 11.54 with a yield of 10%.
- If the yield increases instantaneously from 10% to 10.1%, the approximate percentage price change will be $-11.54 \times 0.001 = -0.01154 = -1.154\%$.

General speaking, the duration we talk about is modified duration!

Maturity	Yield	Yesterday	Last Week	Last Month
3 Month	1.64	1.67	1.64	1.63
6 Month	1.86	1.87	1.88	1.87
2 Year	2.30	2.30	2.36	2.49
3 Year	2.15	2.14	2.17	2.35
5 Year	2.97	2.91	3.09	3.19
10 Year	3.67	3.70	3.81	3.93
30 Year	4.26	4.30	4.42	4.54

Behavior of Price Volatility

- Price volatility increases as the coupon rate decreases.
 - Bonds selling at a deep discount are more volatile than those selling near or above par.
 - Zero-coupon bonds are the most volatile.
- Price volatility increases as the required yield decreases.
 - So bonds traded with higher yields are less volatile.

Behavior of Price Volatility

- For bonds selling above par or at par, price volatility increases as the term to maturity lengthens (see figure on next page).
 - Bonds with a longer maturity are more volatile. (But the *yields* of long-term bonds are less volatile than those of short-term bonds.)
- For bonds selling below par, price volatility first increases then decreases.
 - Longer maturity here cannot be equated with higher price volatility.

Figure 4.1 (Premium bonds and par bonds):
Volatility with respect to terms to maturity

Figure 4.1 (discount bonds):
Volatility with respect to terms to maturity.

Macaulay Duration

- The Macaulay duration (MD) is a weighted average of the times to an asset's cash flows.
- The weights are the cash flows' PVs divided by the asset's price. Formally,

$$MD \equiv \frac{1}{P} \sum_{i=1}^n \frac{iC_i}{(1+y)^i}$$

- The Macaulay duration, in periods, is equal to

$$MD = -(1+y) \frac{\partial P / P}{\partial y} \quad (4.2)$$

The Proof

$$\begin{aligned} \therefore P &= \frac{C}{1+y} + \frac{C}{(1+y)^2} + \dots + \frac{C+F}{(1+y)^n} \\ \therefore \frac{\partial P}{\partial y} &= \frac{-C}{(1+y)^2} + \frac{-2C}{(1+y)^3} + \dots + \frac{-n(C+F)}{(1+y)^{n+1}} \\ \therefore \frac{\partial P}{\partial y} &= -\frac{1}{1+y} \left[\frac{C}{(1+y)} + \frac{2C}{(1+y)^2} + \dots + \frac{n(C+F)}{(1+y)^n} \right] \\ \therefore \frac{\partial P}{\partial y} \frac{1}{P} &= -\frac{1}{1+y} \left[\frac{C}{(1+y)} + \frac{2C}{(1+y)^2} + \dots + \frac{n(C+F)}{(1+y)^n} \right] \frac{1}{P} \\ \text{Define: } MD &= \frac{\frac{C}{(1+y)} + \frac{2C}{(1+y)^2} + \dots + \frac{n(C+F)}{(1+y)^n}}{P} = \frac{\sum_{i=1}^n iC_i}{P} \\ \therefore \frac{\partial P}{\partial y} \frac{1}{P} &= -\frac{1}{1+y} MD \Rightarrow \frac{\partial P / P}{\partial y / 1+y} = -MD \end{aligned}$$

Example:

Duration of 6-Year Eurobond, 1,000 Face Value, 8 Percent Coupon and Market Yields 8%

t	C _t	DF _t	C _t × DF _t	C _t × DF _t × t
1	80	0.9259	74.07	74.07
2	80	0.8573	68.59	137.18
3	80	0.7938	63.51	190.53
4	80	0.7350	58.80	235.20
5	80	0.6806	54.45	272.25
6	1080	0.6302	680.58	4083.48
			1000	4992.71
MD=4992.71/1000=4.993 years				

C is cash flow, DF is discount factor

C++: Macaulay Duration的計算

- Macaulay Duration的計算

$$MD = \frac{1}{P} \left(\sum_{i=1}^n \frac{ic}{(1+r)^i} + \frac{nF}{(1+r)^n} \right)$$

- 利用for loop同時求算 $\frac{1}{P}$ 和 $\sum_{i=1}^n \frac{ic}{(1+r)^i} + \frac{nF}{(1+r)^n}$
- 相乘即為答案

完整程式碼

```
#include <stdio.h>
void main()
{
    int n;
    float c, r, Value=0, Discount, Duration=0;
    printf("請輸入期數:");
    scanf("%d", &n);
    printf("請輸入債息:");
    scanf("%f", &c);
    printf("請輸入利率:");
    scanf("%f", &r);
    for(int i=1; i<=n; i=i+1)
    {
        Discount=1;
        for(int j=1; j<=i; j++)
        {
            Discount=Discount/(1+r);
        }
        Duration=Duration+i*Discount*c;
        Value=Value+Discount*c;
        if(i==n)
        {
            Value=Value+Discount*100;
            Duration=Duration+n*Discount*100;
        }
    }
    Duration=Duration/Value;
    printf("Duration=%f", Duration);
}
```

→ For迴圈: 計算 Duration, Value

→ For迴圈: 計算Discount factor

→ If 條件式: i等於n時,考慮face value

Homework 3

- Program Exercise

課本(C++財務程式設計)第三章習題8, 9。

8.請嘗試使用一些簡單的財務知識，來驗證本章的計算存續期間的範例程式產生的答案是否合理。假定債券支付的債息為0，則其存續期間應為多少？請問當債息提高（或下降），存續期間應提高還是下降？並將推論的結果輸入範例程式中，驗證推論的結果是否和程式的輸出相符合。

Homework 3

9. 在本章實例演練中討論的存續期間 (duration) 稱為 Macaulay duration (MD), 其定義經化簡可得 $\frac{-\partial P / \partial r \times (1+r)}{P}$ 。為了討論債券價格的變化和殖利率變動的關係, 可定義 Modified duration, Modified duration 定義為 $\frac{-\partial P / \partial r}{(1+r)} = \frac{MD}{(1+r)}$ 。請修改本章計算存續期間的範例程式, 計算 Modified duration。請利用程式中已計算出的 Modified duration, 計算當殖利率變動一個 basis point 時, 該債券價格變動的百分比。

Macaulay Duration

- The MD of a coupon bond is less than its maturity.
- The MD of a zero-coupon bond
- The MD of a Consol

MD of a Coupon Bond

- The MD of a coupon bond is

$$MD = \frac{1}{P} \left(\sum_{i=1}^n \frac{iC}{(1+y)^i} + \frac{nF}{(1+y)^n} \right) \quad (4.3)$$

Where C is the period fixed interest flow.

The MD of a zero-coupon bond

- MD of a zero-coupon bond is its **final maturity (n)**.
- Proof: because no cash flows before maturity, the MD is

$$MD = \frac{\sum_{i=1}^n iC_i(1+y)^{-i}}{\sum_{i=1}^n C_i(1+y)^{-i}} = \frac{nC_n(1+y)^{-n}}{C_n(1+y)^{-n}} = n$$

The MD of a Consol Bond

- A consol bond pay a fixed coupon each period but it never matures. (*Maturity date* = ∞)
- The duration of a consol bond is: $MD_c = 1 + \frac{1}{y}$

$$\because P = \frac{C}{y} \Rightarrow C = Py$$

$$\because MD = \frac{\frac{C}{(1+y)} + \frac{2C}{(1+y)^2} + \frac{3C}{(1+y)^3} + \dots}{P} = \frac{\frac{Py}{(1+y)} + \frac{2Py}{(1+y)^2} + \frac{3Py}{(1+y)^3} + \dots}{P}$$

$$= \frac{y}{(1+y)} + \frac{2y}{(1+y)^2} + \frac{3y}{(1+y)^3} + \dots$$

$$\because \frac{1}{(1+y)} MD = \frac{y}{(1+y)^2} + \frac{2y}{(1+y)^3} + \frac{3y}{(1+y)^4} + \dots$$

$$\Rightarrow MD - \frac{1}{(1+y)} MD = \frac{y}{(1+y)} + \frac{y}{(1+y)^2} + \frac{y}{(1+y)^3} + \dots \Rightarrow \frac{y}{(1+y)} MD = \frac{y/(1+y)}{1 - \frac{1}{(1+y)}} = 1 \Rightarrow MD = \frac{1+y}{y} = 1 + \frac{1}{y}$$

Where y is yield to maturity

The MD of Floating-rate instruments

- A floating-rate instrument makes interest rate payments based on some publicized index such as the London Interbank Offered Rate (LIBOR), the U.S. T-bill rate.
- Instead of being locked into a number, the coupon rate is reset periodically to reflect the prevailing interest rate.
- Floating-rate instrument are typically **less sensitive to** interest rate changes than are fixed-rate instrument.

The MD of Floating-rate instruments

- Assume that the fixed coupon rate c in first j period, y in $n-j$ period, also market yield is y now. The first reset date is j period from now, and reset will be performed thereafter.
- Let the principal be \$1 for simplicity. The cash flow of the floating-rate instrument is

$$\underbrace{c, c, \dots, c}_j, \underbrace{y, \dots, y, y+1}_{n-j}$$

- The MD of a floating-rate instrument is $MD_{Fix} - \sum_{i=j+1}^n \frac{1}{(1+y)^{i-1}}$

Denote the MD of an otherwise identical fixed-rate bond.

Homework 4

- Prove that

$$MD_{floating} = MD_{Fix} - \sum_{i=j+1}^n \frac{1}{(1+y)^{i-1}}$$

Where the bond is priced at par, and the principal be \$1 for simplicity.

Conversion

- To convert the MD to be year based, [modify\(4.3\)](#) as follow:

$$\frac{1}{p} \left(\sum_{i=1}^n \frac{i}{k} \frac{C}{(1+\frac{y}{k})^i} + \frac{n}{k} \frac{F}{(1+\frac{y}{k})^n} \right)$$

Where y is the *annual yield* and k is the compounding frequency per annum.

- [Equation \(4.2\)](#) also becomes $MD = -(1+\frac{y}{k}) \frac{\partial P / p}{\partial y}$
- Note from the definition that $MD(\text{in years}) = \frac{MD(\text{in periods})}{k}$

Difference of formulas

- Macaulay Duration: $MD = -\frac{\partial P / P}{\partial y / (1+y)}$
- Modified Duration: $D = \frac{MD}{1+y} = -\frac{\partial P / P}{\partial y}$
- Dollar Duration: $DD = D \times P = -\frac{\partial P}{\partial y}$

Effective Duration

- A general numerical formula for volatility is the effective duration, defined as

$$\frac{P_- - P_+}{P_0(y_+ - y_-)} \quad (4.5)$$

where P_- is the price if the yield is decreased by Δy , P_+ is the price if the yield is increased by Δy , P_0 is the initial price, y is the initial yield, and Δy is small.

- We can compute the effective duration of just about any financial instrument.

Effective Duration

- Most useful where yield changes alter the cash flow or securities whose cash flow is so complex that simple formulas are unavailable
- Duration of a security can be longer than its maturity or negative.
 - Consider a cash flow: -1 @ time 1 and 2 @time 2
 - Consider a cap
- Neither makes sense under the maturity interpretation.

- An alternative is to use $\frac{P_0 - P_+}{P_0 \Delta y}$.

Immunization and MD

- A portfolio immunizes a liability if its value at horizon covers the liability for **small rate changes now**.
- How do we find such a bond portfolio?
 - A bond portfolio whose MD equals the horizon and whose PV equals the PV of the single future liability.
 - At horizon, losses from the interest on interest will be compensated by gains in the sale price when interest rates fall.
 - Losses from the sale price will be compensated by the gains in the interest on interest when interest rates rise

Bond value under three rate scenarios

Immunization

- Assume the liability is L at time m and the current interest rate is y . We are looking for a portfolio such that
 - (1) FV is L at the horizon m ;
 - (2) $\partial FV / \partial y = 0$;
 - (3) FV is convex around y .
- Condition (1) says the obligation is met.
- Conditions (2) and (3) mean L is the portfolio's minimum FV at horizon for small rate changes.

The Proof (1)

- Let $FV \equiv P(1+y)^m$, where P is the PV of the portfolio. Now,

$$\frac{\partial FV}{\partial y} = m(1+y)^{m-1}P + (1+y)^m \frac{\partial P}{\partial y} \quad (4.8)$$

- Imposing Condition (2) leads to

$$m = -(1+y) \frac{\partial P / P}{\partial y} \quad (4.9)$$

- The MD is equal to the horizon m .

The Proof (2)

- Employ coupon bond for immunization, because

$$FV = \sum_{i=1}^n \frac{C}{(1+y)^{i-m}} + \frac{F}{(1+y)^{n-m}}$$

- It follows that

$$\frac{\partial^2 FV}{\partial^2 y} > 0, \text{ for } y > -1 \quad (4.10)$$

- Because the FV is convex for $y > -1$, the minimum value of FV is indeed L.

Example: Immunization by using duration technique

- Suppose that we are in 2007, and the insurer has to make a guarantee payment **\$1,469** to a policyholder in 5 years, 2012. The amount is equivalent to investing \$1,000 at an annually compound rate of 8% over 5 years.
- Strategy1: Buy five-year maturity discount bonds.
- Strategy2: Buy five-year duration coupon bonds.

Strategy1: Buy five-year maturity discount bonds

- If the insurer buy 1.469 units of these bonds at a total cost of \$1000 in 2007, these investment would produce exactly \$1469 on maturity in five years.
- The reason is that the duration of this bond portfolio exactly matches the target horizon for the insurer's future liability.

$$P = \frac{1000}{1.08^5} = 680.58 \Rightarrow \text{total cost} = 1.469 \times 680.58 = 1000$$

$$\text{cash flow in five years} = \$1000 \times 1.469 = \$1469$$

Strategy2: Buy five-year duration coupon bonds.

- The gain or losses on reinvestment income that result from an interest rate change are exactly offset by losses or gains from the bond proceeds on sale.

	YTM fall to 7%	YTM is 8%	YTM rise to 9%
Coupons (5x\$80)	400	400	400
Reinvestment income	60	69	78
Sale of bond at end of the 5th year	1009	1000	991
	\$1469	\$1469	\$1469

Cash matching

Immunitation

- If there is no single bond whose MD match the horizon, a portfolio of two bonds A and B, can be assembled by the solution of

$$1 = \omega_A + \omega_B$$

$$D = \omega_A D_A + \omega_B D_B \quad (\text{See next page})$$

Here, D_i is the MD of bond i and ω_i is the weight of bond i in the portfolio.

- Make sure that D falls between D_A and D_B to guarantee $\omega_A > 0, \omega_B > 0$, and positive portfolio convexity.

$$\text{Set } D = \frac{1}{P} \sum_{i=1}^n \frac{iC_i}{(1+y)^i}$$

$$D_A = \frac{1}{P_A} \sum_{i=1}^{n_A} \frac{iA_i}{(1+y)^i}, \quad D_B = \frac{1}{P_B} \sum_{i=1}^{n_B} \frac{iB_i}{(1+y)^i}$$

(A_i, B_i : cashflow of A and B at i -th period)

$$\therefore W_A D_A + W_B D_B = \frac{W_A}{P_A} \sum_{i=1}^{n_A} \frac{iA_i}{(1+y)^i} + \frac{W_B}{P_B} \sum_{i=1}^{n_B} \frac{iB_i}{(1+y)^i}$$

$$\text{Set } P = W_A P + W_B P$$

we can buy $\frac{W_A P}{P_A}$ units of A , and $\frac{W_B P}{P_B}$ units of B .

$$\text{then } D = \frac{1}{P} \sum_{i=1}^{n_A} \frac{i \frac{W_A P}{P_A} A_i}{(1+y)^i} + \frac{1}{P} \sum_{i=1}^{n_B} \frac{i \frac{W_B P}{P_B} B_i}{(1+y)^i} = \frac{W_A}{P_A} \sum_{i=1}^{n_A} \frac{iA_i}{(1+y)^i} + \frac{W_B}{P_B} \sum_{i=1}^{n_B} \frac{iB_i}{(1+y)^i}$$

$$\therefore D = W_A D_A + W_B D_B$$

In Class Exercise

- The liability has an MD of 3 years, but the money manager has access to only two kinds of bonds with MDs of 1 year and 4 years. What is the right proportion of each bond in the portfolio in order to match the liability's MD?

Limitations of Duration

- Duration matching can be costly.
- Immunitation is a dynamic problem.
 - Because continuous rebalancing may not be easy to do and involves costly transaction fees.
 - There is a trade-off between being perfectly immunized and the transaction costs of maintaining.
- Large interest rate and convexity (see next figure).
 - Duration accurately measures the price sensitivity of fixed-income securities for small change in interest rates.

Convexity

- Convexity is defined as

$$\text{convexity (in period)} \equiv \frac{\partial^2 P}{\partial y^2} \frac{1}{P} \quad (4.14)$$

- The convexity of a coupon bond is positive.
- For a bond with positive convexity, the price rises more for a rate decline than it falls for a rate increase of equal magnitude.
- Between two bonds with the same duration, the one with a higher convexity is more valuable.

Figure 4.6: Linear and quadratic approximation to bond price changes.

Convexity

- The approximation $\Delta P/P \approx -$ (modified) duration \times yield change works for small yield changes.
- To improve upon it for larger yield changes, use

$$\frac{\Delta P}{P} \approx \frac{\partial P}{\partial y} \frac{1}{P} \Delta y + \frac{1}{2} \frac{\partial^2 P}{\partial y^2} \frac{1}{P} (\Delta y)^2 = -\text{duration} \times \Delta y + \frac{1}{2} \times \text{convexity} \times (\Delta y)^2$$

Calculation of Convexity

- Formula:

$$\begin{aligned} CX &= \text{Scaling factor} (\text{The capital loss from 1bp rise} + \text{The capital gain from 1bp fall}) \\ &= 10^8 \left(\frac{\Delta P^-}{P} + \frac{\Delta P^+}{P} \right) \end{aligned}$$

- Example: To calculate convexity of the 8 percent coupon, 8 percent yield, six-year maturity Eurobond that had a price of \$1000:

$$\begin{aligned} CX &= 10^8 \left(\frac{999.53785 - 1000}{1000} + \frac{1000.46243 - 1000}{1000} \right) \\ &= 10^8 (0.00000028) = 28 \end{aligned}$$

Example

- Given convexity C , the percentage price change expressed in percentage terms is approximated by $-D \times \Delta r + C \times (\Delta r)^2 / 2$ when the yield increases instantaneously by $\Delta r\%$.
- For example, if $D = 10$, $C = 150$, and $\Delta r = 2\%$, price will drop by 17% because

$$\Delta P/P = -10 \times 2\% + 1/2 \times 150 \times (2\%)^2 = -17\%$$

In Class Exercise

- Show that the convexity of a n-period zero-coupon bond is $n(n+1)/(1+y)^2$

Immunization (barbell Portfolio)

- Two bond portfolios with varying duration pairs D_A, D_B can be assembled to satisfy $D = \omega_A D_A + \omega_B D_B$. However, which one is to be preferred?
- Let there be n kinds of bonds, with bond i having duration D_i and convexity C_i , where $D_1 < D_2 < \dots < D_n$. We then solve the follow constrained optimization problem:

$$\text{maximize } \omega_1 C_1 + \omega_2 C_2 + \dots + \omega_n C_n$$

$$\text{subject to } \omega_1 + \omega_2 + \dots + \omega_n = 1$$

$$\omega_1 D_1 + \omega_2 D_2 + \dots + \omega_n D_n = D$$

The solution usually implies a **barbell portfolio**, which consists of very short-term bonds and very long-term bonds..

Proof of Convexity $C = W_A C_A + W_B C_B$

$$\frac{\partial^2 P}{\partial y^2} = \sum_{i=1}^n \frac{i(i+1)C_i}{(1+y)^{i+2}} \quad \text{Convexity} = \frac{1}{P} \frac{\partial^2 P}{\partial y^2} = \frac{1}{P} \sum_{i=1}^n \frac{i(i+1)C_i}{(1+y)^{i+2}} \equiv C$$

(Let A_i, B_i : cash flow of A and B at i -th period)

$$C_A = \frac{1}{P_A} \sum_{i=1}^{n_A} \frac{i(i+1)A_i}{(1+y)^{i+2}}, \quad C_B = \frac{1}{P_B} \sum_{i=1}^{n_B} \frac{i(i+1)B_i}{(1+y)^{i+2}}$$

$$\therefore W_A C_A + W_B C_B = \frac{W_A}{P_A} \sum_{i=1}^{n_A} \frac{i(i+1)A_i}{(1+y)^{i+2}} + \frac{W_B}{P_B} \sum_{i=1}^{n_B} \frac{i(i+1)B_i}{(1+y)^{i+2}}$$

Set $P = W_A P_A + W_B P_B$ we can buy $\frac{W_A P}{P_A}$ units of A, and $\frac{W_B P}{P_B}$ units of B

$$\begin{aligned} \text{then } C &= \frac{1}{P} \sum_{i=1}^{n_A} \frac{i(i+1) \frac{W_A P}{P_A} A_i}{(1+y)^{i+2}} + \frac{1}{P} \sum_{i=1}^{n_B} \frac{i(i+1) \frac{W_B P}{P_B} B_i}{(1+y)^{i+2}} \\ &= \frac{W_A}{P_A} \sum_{i=1}^{n_A} \frac{i(i+1)A_i}{(1+y)^{i+2}} + \frac{W_B}{P_B} \sum_{i=1}^{n_B} \frac{i(i+1)B_i}{(1+y)^{i+2}} = W_A C_A + W_B C_B \end{aligned}$$

Lagrange Multiplier Method

function $f(x_1, x_2, \dots, x_n)$

subject to $g(x_1, x_2, \dots, x_n) = 0$

$F(x_1, x_2, \dots, x_n, \lambda) = f(x_1, x_2, \dots, x_n) + \lambda \cdot g(x_1, x_2, \dots, x_n)$

$F_{x_1}(x_1, x_2, \dots, x_n, \lambda) = 0$

$F_{x_2}(x_1, x_2, \dots, x_n, \lambda) = 0$

\vdots

$F_{x_n}(x_1, x_2, \dots, x_n, \lambda) = 0$

$g(x_1, x_2, \dots, x_n) = 0$

A Simple Example

min $f(x, y) = 5x^2 + 6y^2 - xy$

s.t $x + 2y = 24$

$g(x, y) = x + 2y - 24 = 0$

$F(x, y, \lambda) = 5x^2 + 6y^2 - xy + \lambda(x + 2y - 24)$

$F_x(x, y, \lambda) = 10x - y + \lambda = 0 \dots (1)$

$F_y(x, y, \lambda) = 12y - x + 2\lambda = 0 \dots (2)$

$g = x + 2y - 24 = 0 \dots (3)$

根據(1)-(2) 得 $x = \frac{2}{3}y$

$x = \frac{2}{3}y$ 代入(3), 得 $y = 9, x = 6$

Use Lagrange Multiplier Method to obtain the optimal bond portfolio

max $\omega_1 C_1 + \omega_2 C_2 + \dots + \omega_n C_n$

s.t $\omega_1 + \omega_2 + \dots + \omega_n = 1$

$\omega_1 D_1 + \omega_2 D_2 + \dots + \omega_n D_n = D$

$g_1(\omega_1, \omega_2, \dots, \omega_n) = \omega_1 + \omega_2 + \dots + \omega_n - 1 = 0$

$g_2(\omega_1, \omega_2, \dots, \omega_n) = \omega_1 D_1 + \omega_2 D_2 + \dots + \omega_n D_n - D = 0$

$F(\omega_1, \omega_2, \dots, \omega_n) = \omega_1 C_1 + \omega_2 C_2 + \dots + \omega_n C_n +$

$\lambda_1(\omega_1 + \omega_2 + \dots + \omega_n - 1) + \lambda_2(\omega_1 D_1 + \omega_2 D_2 + \dots + \omega_n D_n - D)$

Example: Immunization (Convexity is desirable)

- Consider a pension fund manager with a 15-year payout horizon. To immunize the risk of interest rate changes, the manager purchase bonds with a 15-year duration. Consider two alternative strategies to achieve this:
- Strategy1: Invest 100 percent of resources in a 15-year deep-discount bond with an 8 percent yield. (Bullet portfolio)
- Strategy2: Invest 50 percent in the very short-term money market and 50 percent in 30-year deep-discount bond with an 8 percent yield. (Barbell portfolio)

Example: Immunization (Convexity is desirable)

- Strategy1:
Duration =15 $\Delta y=5\%$
Convexity =206
value of the convexity = $1/2 \times \text{convexity} \times \Delta y^2 = 25.75\%$
 - Strategy2:
Duration = $1/2 \times 0 + 1/2 \times 30 = 15$
Convexity = $1/2 \times 0 + 1/2 \times 797 = 398.5$
Value of the convexity = $1/2 \times \text{convexity} \times \Delta y^2 = 49.81\%$
- High convexity is more valuable
- The manager may seek to attain greater convexity in the asset portfolio than in the liability portfolio, as a result, both positive and negative shocks to interest rates would have beneficial effects on the net worth.

Categories of Immunization

- Cash matching
- Rebalancing

Cash matching

- Cash matching is the approach that a stream of liability can always be immunized with a matching stream of zero-coupon bonds.
- Two problem with this approach are that (1) zero-coupon bonds may be missing for certain maturity.(2) they typically carry lower yield.
- Recall example (Immunization by using duration technique).

Rebalancing

- Immunization has to be rebalanced constantly to ensure that the MD remains matched to the horizon.
- The MD decreases as time passes.
- But, except for zero-coupon bonds, the decrement is not identical to that in the time to maturity.
 - Consider a coupon bond whose MD matches horizon.
 - Since the bond's maturity date lies beyond the horizon date, its MD will remain positive at horizon.
 - So immunization needs to be reestablished even if interest rates never change.

Hedging

- Hedging aims to offset the price fluctuations of the position to be hedged by the hedging instrument in the opposite direction, leaving the total wealth unchanged.
- Define dollar duration as

$$DD \equiv \text{modified duration} \times \text{price}(\% \text{ of par}) = -\frac{\partial P}{\partial y}$$

- The approximate dollar price change per \$100 of par value is

$$\text{price change} \approx -\text{dollar duration} \times \text{yield change}$$

Hedging

- Because securities may react to interest rate changes differently, we define yield beta to measure relative yield changes.

$$\text{yield beta} \equiv \frac{\text{change in yield for the hedged security}}{\text{change in yield for the hedging security}}$$

- Let the hedge ratio be

$$h \equiv \frac{\text{dollar duration of the hedged security}}{\text{dollar duration of the hedging security}} \times \text{yield beta} \quad (4.13)$$

- Then hedging is accomplished when the value of the hedging security is h times that of the hedged security.

Example 4.2.2

- Suppose we want to hedge bond A with a duration of seven by using bond B with a duration of eight. Under the assumption that yield beta is one and both bonds are selling at par, the hedge ratio is $7/8$. This means that an investor who is long \$1 million of bond A should short $7/8$ million of bond B.
